Disclaimer on biological nomenclature and use of preprints

The preprints are preliminary versions of works accessible electronically in advance of publication of the final version. They are not issued for purposes of botanical, mycological or zoological nomenclature and **are not effectively/validly published in the meaning of the Codes**. Therefore, nomenclatural novelties (new names) or other nomenclatural acts (designations of type, choices of priority between names, choices between orthographic variants, or choices of gender of names) **should NOT be posted in preprints**. The following provisions in the Codes of Nomenclature define their status:

International Code of Nomenclature for algae, fungi, and plants (ICNafp)

Article 30.2: "An electronic publication is not effectively published if there is evidence within or associated with the publication that its content is merely preliminary and was, or is to be, replaced by content that the publisher considers final, in which case only the version with that final content is effectively published." In order to be validly published, a nomenclatural novelty must be effectively published (Art. 32.1(a)); in order to take effect, other nomenclatural acts must be effectively published (Art. 7.10, 11.5, 53.5, 61.3, and 62.3).

International Code of Zoological Nomenclature (ICZN)

Article: 21.8.3: "Some works are accessible online in preliminary versions before the publication date of the final version. Such advance electronic access does not advance the date of publication of a work, as preliminary versions are not published (Article 9.9)".

16 **Abstract**

17 Varied responses of the diverse gut microbiota impact the host nutrient metabolism
18 and disease immunity. The reason and the impact behind the low diversity level of gut
19 microbiota giant panda are yet to be explored. The current study is an attempt to
20 highlight the impact of intestinal type and diet on gut microbiota diversity of giant
21 pandas. A multi-species comparison (n=73) was conducted to analyze the effects of
22 different diets and intestinal type on gut microbiota function of giant panda using
23 PICRUS_t method. The gut microbiota of giant panda was significantly lower than
24 herbivores and carnivores provided with same diets and intestinal type respectively.
25 Moreover, giant panda exhibit significantly reduced microbiota on high-fiber bamboo

26 culm diet than bamboo shoot and leaf. The low diversity of gut microbiota constraint
27 nutritional metabolic function of giant panda including rate of energy and amino acid
28 metabolism. These results showed that the short intestinal tract and high fiber diet
29 diminishes the gut microbiota diversity and metabolic function of giant pandas.

32

33 **Introduction**

34 Gut microbiota (GM) refers to the assembly of complex and dynamically changing
35 microbial community inhabits the gut, and closely associated with nutrient metabolism
36 and immunity of the host (Kelly et al. 2005; Ley et al. 2006). A highly diverse gut
37 microbiota generally confers benefit to host health (Cotillard et al. 2013). Previous
38 research demonstrated that giant panda (*Ailuropoda melanoleuca*) harbor significantly
39 lower gut microbiota diversity than other herbivores, carnivores and omnivores
40 mammals (Xue et al. 2015; Guo et al. 2020). The factors contributing this constraint in
41 the microbiota diversity is however remain unknown, nor its impact on the giant panda
42 nutrient metabolism.

43 The giant panda, a typical vegetarian carnivore specie feed exclusively on high-
44 fiber bamboo. (Dierenfeld et al. 1982; Viswanathan 2010). The anatomy of the giant
45 panda's gastrointestinal tract is similar to other clades of carnivores with short intestinal
46 tract and not used to ferment fibers (Dierenfeld et al. 1982; Guo et al. 2018b). Evidence
47 predicated the transition of giant pandas from omnivorous into bamboo-eating species
48 in the mid-Holocene (Han et al. 2019) albeit it still belongs to the Ursidae family
49 (Krause et al. 2008; Liu et al. 2008). Comparative analysis of panda with in other clades
50 of omnivores and herbivores revealed that the gut microbiota of pandas constituted

51 significantly lower abundance of cellulase genes and higher abundance of
52 hemicellulase genes (Zhang et al. 2018). Therefore, the low gut microbial diversity of
53 giant pandas is proposed to be associated with intestinal tract and dietary interventions.
54 Yet sound evidences are highly missing. It is an effective method to investigate the
55 effects of intestinal and nutritional factors on gut microbiota on the basis of dietary
56 interventions in multiple animal clades (Muegge et al. 2011; Sanders et al. 2015; Vital
57 et al. 2015). Recently, comparison of giant panda with other species of carnivores,
58 omnivores and herbivores has been the focus of the research, yet the data available is
59 not sufficient, especially for herbivores (less than 4 animal samples) (Zhu et al. 2011;
60 Xue et al. 2015; Guo et al. 2020). The current study is an attempt to unravel the factors
61 behind the low gut microbiota diversity in the panda by comparing them with other
62 herbivores, omnivores and carnivores (21, 11, 7 individuals respectively). The potential
63 functions of the gut microbiota repertoire were theoretically tested by PICRUSt
64 (Phylogenetic Investigation of Communities by Reconstruction of Unobserved States)
65 (Langille et al. 2013). The results will broaden the understanding and knowledge
66 pertaining the giant panda research, and put insight into the transition of diet and
67 evolution in the giant panda.

68

69 **Materials and methods**

70 **Raw data processing and OTU assigning**

71 The 16S rRNA sequencing data of feces were retrieved from 27 captive giant
72 pandas fed on shoot, leaf and culm, from our previous study (Yan et al. 2021), and 7
73 wild giant panda fecal samples data were generated by referring to the open released
74 database including clone library (Zhu et al. 2011). The 16S rRNA gene pyrosequencing
75 data was generated from 7 carnivorous, 11 omnivorous, and 21 herbivorous animal

76 fecal samples (Table 1) (Muegge et al. 2011; Zhu et al. 2011). A total of 73 individual's
 77 gene gut microbiota data was included in current study. The obtained sequences were
 78 aligned and merged with sequences from Greengenes database, and the operational
 79 taxonomic units (OTUs) were delineated at 97% sequence identity by using UCLUST
 80 in QIIME (Edgar 2010). We excluded 4 wild pandas sequence datasets with less than
 81 500 raw reads per sample to avoid the loss of too much data during subsequent analysis,
 82 and conducted comparative analysis on 69 samples.

87

88 **The alpha and beta diversity analysis**

89 Referred to the variation in sequencing results of different samples, a corrected
 90 sequencing depth was adopted. The OTU abundance matrix of all the samples unified
 91 to the minimum sequencing depth, and the rarefied to the consistent sequencing depth.
 92 Flattened data is analyzed to maximize consistency and reliability depicting in both
 93 alpha and beta diversity. For comparative evaluation of diversity, all samples in the
 94 OTU abundance matrix were randomly re-sampled at the minimum sequencing depth
 95 of 90% to adjust the disparities caused by sequencing depth. Furthermore, QIIME
 96 (Quantitative Insights in to Microbial Ecology) software was used for calculation of the
 97 diversity index for each sample (Caporaso et al. 2010). QIIME pipeline is used to plot
 98 the data obtained from UniFrac distance Principal coordination analysis (PCoA)
 99 (Thongboonkerd and Saetun 2007).

100

101 **Prediction of microbial metabolic function**

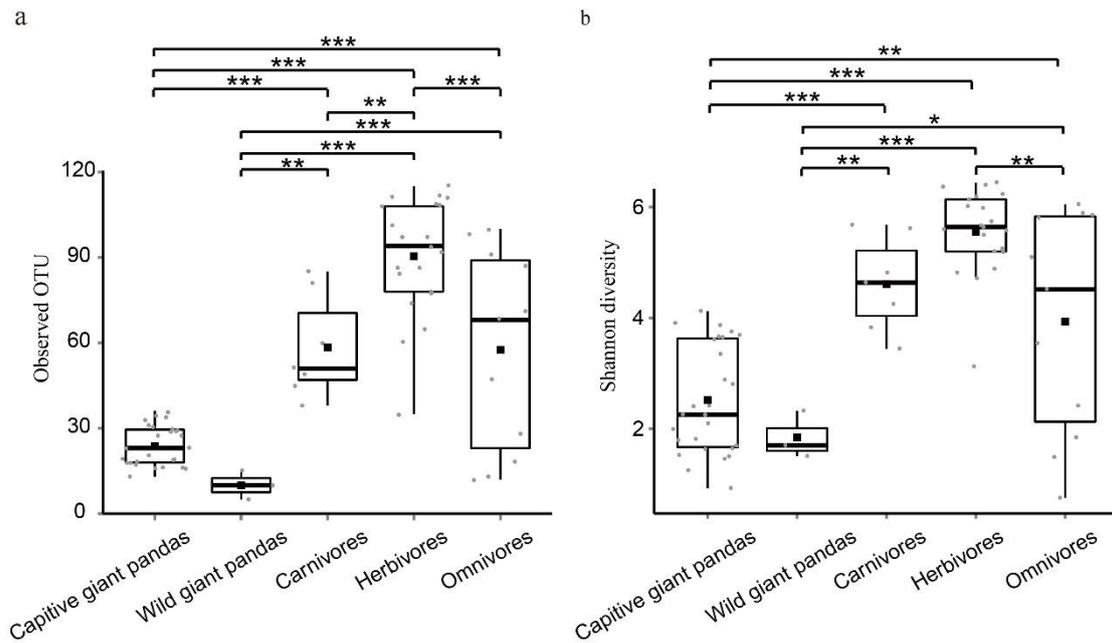

102 The PICRUST was applied to predict the metabolic function of gut microbiota
103 inferred from KEGG pathway database (<http://www.genome.jp/kegg/pathway.html>)
104 (Langille et al. 2013). Existing gene sequencing data were compared with known
105 metabolic functions in the microbial reference genome database to predict the metabolic
106 functions of gut microbiota. The variation of 16S rRNA gene copy number among
107 different species was also considered in the prediction process, and the species
108 abundance data in the original data were corrected to make the prediction results more
109 accurate and reliable (Langille et al. 2013).

110

111 **Results**

112 **The difference of gut microbiota composition by 16S rRNA sequencing**

113 According to 97% sequence similarity, the obtained sequences were compared with
114 Greengenes database and divided into 1790 OTUs. The gut microbiota composition
115 was significantly different between the giant panda and other herbivores, omnivores
116 and carnivores. The α -diversity index showed that the gut microbiota richness and
117 diversity of captive and wild giant pandas were not significantly different, yet both were
118 significantly lower than other herbivores, carnivores and omnivores (both $P < 0.05$).
119 The herbivores exhibit the highest gut microbiota richness and diversity than
120 omnivorous animals ($P < 0.01$). There found no significant difference between
121 omnivorous and carnivorous animals (Fig. 1).

122

123 Fig. 1. Comparison of α -diversity of gut microbiota in captive, wild giant pandas

124 and other herbivorous, omnivorous and carnivorous. * $P < 0.05$, ** $P < 0.01$, *** P

125 < 0.001

126

127 Moreover, the captive giant pandas and other feeding species were found clustered

128 together when only presence/absence of gut microbiota species were taken into account

129 rather than their abundance. This indicates that species with different feeding habits

130 exhibit distinct microbial communities (Fig. 2a). Referred to the gut microbial

131 abundance, samples from the shoot, leaf and culm bamboo diet clearly clustered into

132 three groups in the PCoA, the distance between the leaf and the shoot group was similar,

133 but the distance from the culm group was longer (Fig. 2b). The gut microbiota of pandas

134 feeding purely on culm was similar to wild giant pandas and four omnivores: the

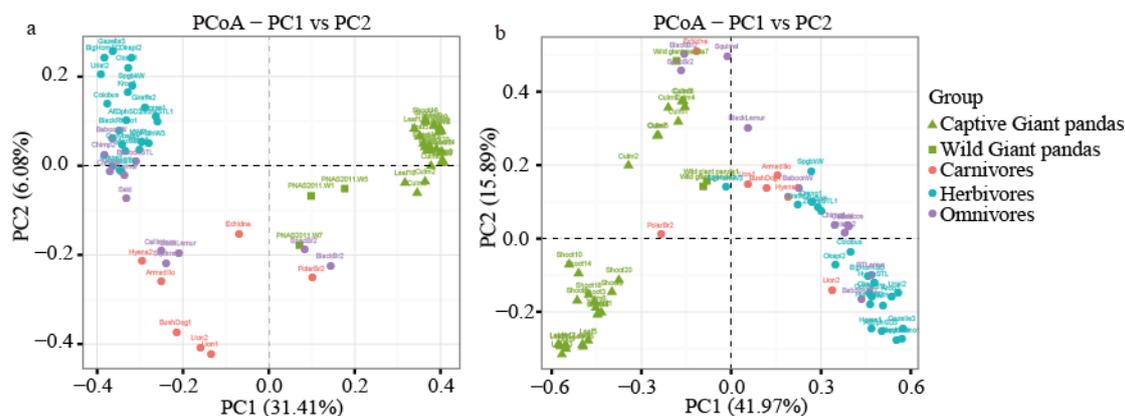

135 spectacled bear (*Tremarctos ornatus*), the American black bear (*Ursus americanus*), the

136 Prevost's squirrel (*Callosciurus prevostii*) and the black lemur (*Eulemur macaco*

137 *macaco*). Interestingly, the gut microbiota greatly differed between the giant panda and

138 herbivores (Fig. 2 a&b) although it is a vegetarian species. In general, the gut microbes
 139 of captive pandas were markedly different from those of other mammals due to their
 140 distinct diet in captivity.

 144 unweighted and (b) weighted UniFrac distances.

145

146 Predict gene function of gut microbiota by PICRUST

147 We used PICRUST to predict 16S rRNA gene sequences in KEGG functional
 148 spectrum database. The giant Panda represented similar gut microbiota abundance to
 149 other animal in lipid metabolism at the second level of the metabolism pathway, but
 150 exhibited lower abundance in energy metabolism, amino acid metabolism, enzyme
 151 family, cofactors and vitamins (Fig. 3). In carbohydrate metabolism, captive giant
 152 pandas had the lowest abundance, but data was non-significant (Fig. 3). The gut
 153 microbiota of giant panda showed the lowest abundance of immune hemostasis by
 154 annotation at the second level of the organismal systems pathway, which is significantly
 155 lower than herbivores ($P < 0.001$, Fig. 4).

176 **Discussion**

177 The findings of the current study revealed that herbivore and carnivore harbor the
178 highest and lowest gut microbiota diversity upon treatment with different diet
179 interventions ($P < 0.05$, Fig. 1). These results confirm the findings of previous studies
180 in different animals (Ley et al. 2008; Xue et al. 2015; McKenney et al. 2018). The panda
181 constitutes a shorter intestinal track as compared to the high-fiber plant eating herbivore
182 with a total length of 6.05 meters (3.41-7.30 meters), about 4.3 times of the body length,
183 in contrast to 10-22 times of body length in herbivores (Raven 1936; Davis 1964;
184 Keymer 1976). The gut microbiota diversity of the panda is significantly lower than
185 that of herbivores species ($P < 0.05$, Fig. 1). Herbivores have rumen and longer
186 intestines, endorsing abundant microbial colonization (Fan et al. 2020). The short
187 intestinal tract of giant panda cannot adequately accommodate gut microbiota
188 colonization, resulting in low diversity.

189 Giant pandas possess a typical carnivore-like short intestinal tract, yet possess
190 significantly lower gut microbiota diversity as compared to carnivores ($P < 0.05$, Fig.
191 1). This might be related to its bamboo-eating habit. Moreover, captive giant pandas
192 feed primarily on single part of bamboo including shoot, leaf and culm (rich in crude
193 protein, ether extract and crude fiber respectively, $P < 0.05$), in specific seasons (Wang
194 et al. 2017; Yan et al. 2021). During the bamboo culm eating season, the giant panda
195 tends to prioritize the fiber intake than that of bamboo leaf and shoot (3225.40 ± 626.34 ,
196 978.95 ± 119.90 , 357.78 ± 83.17 g/d respectively) ($P < 0.05$) (Wang et al. 2017), yet it
197 displayed the lowest diversity in respective season. However, a seasonal diet switch
198 from bamboo culm eating to high protein bamboo shoot diet displayed the highest
199 diversity ($P < 0.05$) in captive giant pandas (Yan et al. 2021), suggesting that high-fiber

200 diet causes a lower gut microbiota diversity in the giant panda. Similar results are found
201 in the red panda (*Ailurus fulgens*) and bamboo-eating lemurs (*Hapalemur griseus*), both
202 displayed comparatively lower gut microbial diversity than other carnivorous species
203 (McKenney et al. 2018; Guo et al. 2020). Moreover, the bamboo-eating lemurs exhibit
204 similar gut microbiota to giant panda than that its sister species, the ringtail lemur
205 (*Lemur catta*) (McKenney et al. 2018). The effect of high fiber on the gut microbiota is
206 also demonstrated in captive giant panda cubs, with their gut microbiota diversity level
207 significantly declined after diet switch from a high-protein milk to a high-fiber bamboo
208 diet at weaning (Guo et al. 2018a; Guo et al. 2020). Similar results are illustrated in the
209 red panda cubs transiting diet during weaning time (Williams et al. 2018). However, a
210 recent study on dietary transition of giant panda cubs reported that the elevated
211 consumption of fibrous diet decreased the richness and increased the diversity of gut
212 microbiota (Jin et al. 2021). The distinct outcome is expected owing to different dietary
213 supplements, such as bamboo shoots, carrots and steamed bread (Jin et al. 2021).
214 Similarly, the adult red pandas feeding predominantly on bamboo displayed lower
215 diversity than the weaned cubs feeding on the mix diet of milk and bamboo (Williams
216 et al. 2018). Therefore, an exclusive high-fiber bamboo diet had a significant impact on
217 gut microbiota.

218 Diet fiber plays an important role in maintaining gut microbial diversity, and it is
219 suggested to have favorable effect on the gut microbial diversity both in animals and
220 human being (Sonnenburg and Sonnenburg 2014; Sonnenburg et al. 2016). However,
221 all aforementioned studies were normal diet oriented and completely different from the
222 panda diet, with an appropriate amount of fat, simple carbohydrates, and with smaller
223 fiber composition (Sonnenburg and Sonnenburg 2014; Sonnenburg et al. 2016). The
224 dietary switch of mice from milk (dominant) and supplementary foods to 50% bamboo

225 powder indicated a substantial increase in gut microbial diversity of mice increased, but
226 decreased when the bamboo content increased to 80% (Guo et al. 2020), suggesting
227 that a diet with excess fiber and low protein content is not conducive to maintaining gut
228 microbial diversity. Accordingly, in the high-fiber bamboo culm consumption period,
229 adequate amount of bamboo shoots should be provided to supplement protein intake to
230 maintain the diversity of gut microbes. However, giant pandas pose high digestibility
231 for fiber in high-fiber bamboo culm diet (Wang et al. 2017), and cellulose content in
232 bamboo exhibit positive correlation with the relative abundance of *Clostridium* in the
233 intestinal tract of giant pandas ($P < 0.05$) (Jin et al. 2020). Therefore, the high-fiber diet
234 steadily decreases the gut microbiota of giant pandas, but a few bacteria attempted to
235 enhance fiber digestion and improve the utilization rate of fiber for energy supply.

236 Diet shifts alters the gut microbes, which in turn affect the host health and
237 physiological functions (Zhernakova et al. 2016). The habitat of modern giant panda is
238 only a small part of the area inhabited by ancient giant panda. Carnivores, herbivores
239 and giant pandas obviously inhabited the three distinct ecological niches, with the giant
240 panda harboring the lowest gut microbial diversity, probably due to the present giant
241 panda exclusively eating bamboo (Han et al. 2019). Despite showing interest in eating
242 bamboo, the modern giant panda get 48~61% of its energy from protein, 23~39% from
243 carbohydrate and 13~16% from fat. The proportion of energy intake via protein
244 consumption is much higher than that of herbivores, and very similar to that of
245 carnivores such as lions and tigers (Nie et al. 2019). In the bamboo shoot-eating period,
246 the butyrate-producing bacterium *Clostridium butyricum* was more abundant in the gut
247 microbiota of the panda, and their body weight increases significantly. Transplant
248 experiment in the mice further proved this point (Huang et al. 2022). Thus, the bamboo
249 shoot period is the key period for the giant panda to replenish energy and nutrients

250 (Huang et al. 2022). The protein-rich of bamboo shoot diet will lead to significant
251 increase in the gut microbiota richness and diversity of giant pandas (Yan et al. 2021),
252 indicating that the nutrition source of protein depicted better utilization.

253 The lowest gut microbiota diversity of giant panda results in a significant variation
254 in the in the overall gut microbial structure composition as compared to other mammals
255 (Fig. 2). Mammals on the same feeding habits produce similar types of gut microbes,
256 but reported differences in relative abundance (Fig. 2). Thus, gut microbiota abundance
257 exhibited positive correlation with nutrient intake. The gut microbiota of the giant
258 pandas rapidly reacts to the altered diet. (Yan et al. 2021), indicating that this gut
259 microbiota can elicit rapidly proliferation according to the nutrient source and play
260 digestive and metabolic functions.

261 Gut microbiota plays a potential role in maintaining energy balance (Clemmensen
262 et al. 2017). The gut microbiota function differs significantly between the giant pandas
263 and other mammals. The captive giant pandas possess the lowest level of energy
264 metabolism, amino acid metabolism and enzyme spectrum of gut microbiota as
265 compared to other animals on normal diet ($P < 0.05$, Fig. 3). However, there is reported
266 no difference between the gut microbiota function of giant panda and other species in
267 lipid metabolism (Fig. 3). The low intake of fat in these species indicated that fat in
268 food is not the main source of energy. Gut microbiota stimulates the development and
269 regulation of mucosal immune hemostasis. It plays a central role in a variety of
270 physiological functions, including regulating inflammatory signaling and preventing
271 infection (Pagliari et al. 2018). Low microbial diversity has been identified as a risk
272 factor for different chronic diseases, such as intestinal inflammatory diseases, obesity
273 and insulin resistance (Le Chatelier et al. 2013; Crovesy et al. 2017; Statovci et al. 2017;
274 Sokol et al. 2018). Giant pandas possess reduced gut microbiota diversity (Fig.1),

275 speculated the low level of relative abundance of immune system function genes, which
276 was significantly lower than that of herbivores with higher gut microbiota diversity (Fig.
277 4).

278 Spanning long evolutionary history, the host mammals and their indigenous
279 microbial communities have co-evolved (Ley et al. 2008). Gut microbiota-host
280 interactions contribute to the maturation of the host immune system and regulate its
281 systemic response (D'Amelio and Sassi 2018). Endangered species that feed on bamboo
282 such as the giant panda, bamboo lemur and the red panda have developed unique
283 adaptation in the gut microbiota to a high-fiber diet (McKenney et al. 2018). Because
284 the constantly changing foraging strategies of different endangered wild animals, a
285 perspective of natural diet for raising and management of captive wild mammals require
286 evidence based knowledge of nutrient-species relationship and to understand the
287 detailed intricacies for their implementation. Bamboo shoots were thought to be more
288 appropriate for giant panda than bamboo culms because of their higher crude protein
289 and crude fat content (Wang et al. 2017). However, wild giant pandas chose bamboo
290 culm as a food source in the proestrus and estrus period of giant pandas (Schaller et al.
291 1985; Taylor and Zisheng 1987; Fuwen et al. 2011; Wei et al. 2017). And it has been
292 reported that adding crude fiber in animal diet during estrus could have productive
293 effects such as increased gonadotrophin concentration, improve oocyte quality and
294 maturity, and increase embryo survival (Ferguson et al. 2007; Weaver et al. 2013).
295 Owing to protection endangered wild animals, captive institutions should broaden their
296 understanding dietary rules and come up with the best dietary plan to raise and maintain
297 them.

298 In conclusion, comparative analysis of the gut microbiota diversity level of giant
299 panda and other diet feeding animals indicated low level of diversity in gut microbiota

300 of because of its short intestinal tract and high dietary fiber content. The low diversity
301 and community richness of giant panda gut microbiota accounted for reduced level of
302 energy and amino acid metabolism. These findings have important implications for
303 understanding how high-fiber dietary strategies affect host-microbiome relationships.
